

Response

The graph below shows the wildfires that have occurred in the past decade. The National Parks of Canada Fire Protection Regulations are controlled by the Canadian government to authorize parks and forests to manage and help reduce wildfire risks by restricting activities that might increase the possibility of fires. Parks Canada's National fire management program is prioritizing communities safety while restoring the landscape for the ecosystems health and the environment. Helicopters and emergency fire departments are located near forests because if wildfire rates are high they would immediately take extra care and caution and alert residents nearby. As you can see, this law isn't reducing wildfires rates. Because it is not ONLY the residents that are increasing wildfires, it is in fact climate change. Climate change is affecting the environment by people all over the world and nobody is taking action. This clearly shows that the law/project isn't effective and indeed insufficient.

Seasonal fire occurrence
