

Response

An "Evidence" block (for laws/stats).

The rising ocean temperatures caused by climate change is affecting the Nova Scotia lobster populations which threatens the fishing industry as lobster is one of the vital pillars of the Nova Scotia fishing economy. The two main components in this issue is the drastically rising ocean temperatures and the lobster's sensitivity to heat. Due to this issue the lobsters are slowly migrating northward toward Newfoundland where there are cooler and deeper waters. As warmer water for lobsters mean affecting grow and higher disease rates. Stats from the DFO (Fisheries and Oceans Canada) show strong and sustainable stocks for the lobster industry but data indicates that there are a lot of long-term risks for the lobsters like disease and habitat shifts if the oceans temperature keeps rising. Furthermore, The Fisheries Act plays an important role in setting the primary regulatory framework for managing all of Canada's valuable fishery. This makes this have a direct relation to our issue as the lobster industry's response to the rising ocean temperatures is by setting conservation measures to address the changes in lobster behavior, habitats and distribution. Even though the current warming waters created a sweet spot for fishermen, the DFO may change when and where the fishing takes place due to the potential decreased or shifted populations of lobsters in the future.

The Laws/stats especially the Fisheries Act is developing as it does address issues related to the lobsters but current policies haven't fully addressed climate-change related impacts on the fisheries.
